The present invention relates to a semiconductor device having a non-volatile memory cell having a floating gate electrode and a control gate electrode, and more specifically to a fabrication process thereof. The term "semiconductor device" used in this specification means a device which is fabricated by a semiconductor process. In the present specification, a memory device which is capable of storing information by accumulating electric charges in a floating gate or a control gate electrode of a memory cell is called a "non-volatile memory device" or "non-volatile semiconductor device". A conventional non-volatile memory cell of this kind is disclosed in, for example, U.S. Pat. No. 5,029,130. In the memory cell disclosed in this patent, a field oxide film 12, a gate insulation film 14, a floating gate electrode 16, and a control gate electrode 18 are formed as shown in FIG. 1. Further, a select gate insulation film 19 and a select gate electrode 20 are formed on the upper surface of the substrate 10. In the conventional non-volatile memory cell, the upper surface of the substrate 10 is divided by the field oxide film 12 into an N-well region 12 and a P-well region 14. Therefore, the floating gate electrode 16 and the control gate electrode 18 extend over the P-well region 14 and the N-well region 12 and also extend in the word direction. Thus, the substrate 10 cannot be well symmetric with respect to the center of the memory cell. In the conventional non-volatile memory cell, the substrate potential is varied due to the parasitic capacity of the bit line BL and the control gate electrode 18, which is undesirable for operation. In addition, since the floating gate electrode 16 and the control gate electrode 18 are formed for each and f678ea9f9e
